Effects of Core Stability Exercises, Lumbar Lordosis and Low-Back Pain: A Systematic Review

Gojko Skundric¹, Veljko Vukicevic¹, Nikola Lukic¹
¹University of Novi Sad, Faculty of Sport and Physical Education, Novi Sad, Serbia

Abstract
Core stability has a very positive effect on the prevention of lumbar lordosis and lower back pain. The main focus of this paper was on a review of the available literature on the influence of trunk stability on lower back pain and lumbar lordosis. The two electronic databases researched for collecting articles are PubMed and ScienceDirect. A search was conducted by title, taking a predefined combination of the following keywords into account: low back pain, core stability, training, sports. Screening processes are summarized through a PRISMA flow chart. 408 studies were identified, of which 20 met the inclusion criteria. It was concluded that exercise on the stability of the pelvic nucleus and muscles is recommended as the simplest and most favorable prevention of lower back pain and lumbar lordosis. The stability of the nucleus helps to overcome the main causes and deprive the body of functional disorders and pain.

Keywords: Low Back Pain, Core Stability, Training, Sports

Introduction
Lower back pain (LBP) is a growing problem among people around the world, especially in underdeveloped countries, resulting in a very large impact on people’s quality of life (Buchbinder et al., 2013; Haryono, Kawilarang, & Prastowo, 2019). The increase in the impact left by LBP, observed in recent research, shows that LBP is among the ten most significant causes of disability (Collaborators, 2015). It has been noted that the prevalence of LBP by the end of life is found in about 84%, and almost 23% suffer from constant pain (Airaksinen et al., 2015), but this is very variable and depends on the specifics of the population under study. The economic issue of early retirement and loss of productivity, related to LBP, is alarming due to the high costs for individuals and the state (Buchbinder et al., 2013). The etiology of LBP multiple factor with previous LBP, frequent bending and twisting, prolonged static positions, anxiety, depression and somatization associated with the development of the condition (McIntosh & Hall, 2008; van Middelkoop et al., 2010) Musculoskeletal risk factors are also associated with LBP and they can be identified and addressed through the potential discovery of a mechanism by which LBP can be successfully cured. Also, the right identification of risk factors of the musculoskeletal system can indicate the mechanism by which the occurrence of LBP can be prevented, as well as lead to a reduction in socio-economic costs.

It has been shown that lumbopelvic-hip muscle dysfunction (muscle core) increases the load on the spine and reduces the stability of the spine with altered patterns of recruitment of basic muscles, which is a sign of LBP, especially in the chronic form (Hodges & Richardson, 1998). Therefore, abnormal lower limb function is not recommended in order to mitigate the impact force and affect the spinal load with proximal and distal dysfunction in the lower limbs, which contributes to the increase in LBP. Feet that are in increased pronation (Botte, 1981; Builder & Marr, 1980; Cibulka, 1999) and shortened hind leg muscles (Mierau, Cassidy, & Yong-Hing, 1989; Kujala, Salminen, Taimela, Oksanen, & Jaakkola, 1992) affect a high risk of getting LBP. Feet that are in great pronation cause the tibia and femur to rotate inward and lead to APT (anterior pelvic tilt) (Kujala et al., 1992; Khamis & Yizhar, 2007). When the pelvis is in an altered position, sciatic nerve entrapment can very often occur, because the piriformis muscle is overloaded (Botte, 1981; Cibulka et al., 1999) and shortened hind leg muscles (Mierau, Cassidy, & Yong-Hing, 1989; Kujala, Salminen, Taimela, Oksanen, & Jaakkola, 1992) affect a high risk of getting LBP. Feet that are in great pronation cause the tibia and femur to rotate inward and lead to APT (anterior pelvic tilt) (Kujala et al., 1992; Khamis & Yizhar, 2007). When the pelvis is in an altered position, sciatic nerve entrapment can very often occur, because the piriformis muscle is overloaded (Botte, 1981; Cibulka et al., 1999). In addition, it is suggested that the changed position of the pelvis should load the intervertebral discs, increasing the pain (Gurney, 2002; Tateuchi, Wada, & Ichihashi, 2011). Tight tendon muscles can reduce lumbar lordosis, potentially reducing force absorption and thus increasing the chances of LBP (Alston, Carlson, Feldman, Grimm, & Gerontinos, 1966).

If there are changes in the curvature of the spine, very often there
are pains in certain parts of the back. Lumbar lordosis is one of the most important parts of the spinal pillar that has special importance due to the unique position and having direct contact with the pelvis. It should be paid special attention to the spine in order to have a good physical condition (Kendall, McCreary, Provance, Rodgers, & Romani, 2005). In addition to the bones, ligaments, muscles, and disks vertebrae have also a key role in lordosis formation. Without muscle action, pelvic girdle performance hasn’t sufficient stability (Hodges & Moseley, 2003). The Central stabilization of the vertebral column is supported by special muscles such as multifidus, transversus abdominis, and internal muscles in trunk. These muscles act late in patients who suffered from hyper lordosis (Wagner, Liebeatrau, Schinowski, Wulf, & de Lussanet, 2012). The muscles provide stability of vertebrae in a focal form (Hodges & Moseley, 2003). Decreased strength of one of the muscles of the lumbar-pelvic region affects the change in the position of the pelvis, which disturbs the balance of this part of the body (Norris, 2008) and thus a person can be prone to musculoskeletal disorders (Bouchard & Tetreault, 2000). Biomechanical and clinical studies have shown that muscles can provide stabilization of segments by controlling movement in the neutral zone, and physiological boundaries can be re-established with adequate muscle control (Danneels et al., 2001). Increased lumbar lordosis, if viewed from the mechanical side, is closely related to increased pain in the lower back (von Lackum, 1924; El-Hamalawy, 2011). There are very different factors that cause lumbar lordosis. Some studies have shown that the range of lumbar lordosis is affected by age and sex, movement in the center of mass such as pregnancy or obesity (El-Hamalawy, 2011; Lee, Jung, & Lee, 2013). Exercise is accepted increasingly popular to correct and refine such deformities. Stabilization of the lumbar-pelvic region is improved by exercise, which affects the correct posture and at the same time improves muscle function (Lee et al., 2013; Kofotolis & Kellis, 2006). Some studies suggest that people with low back pain should refrain from certain back exercises, instead of focusing on non-specific physical activities that would improve the psychological state and largely eliminate the pain (Hurwitz, Morgenstern, & Chiao, 2005). This systematic review aimed to identify and point out exercise models that can be applied preventively in a population that may be or is already exposed to problems with lumbar lordosis and lower back pain.

**Method**

**Literature Search Strategy**

To ensure a transparent and complete report, the Preferred Reporting Items For Systematic Reviews (PRISMA) guidelines were followed for conducting a systematic review (Moher et al., 2009). Two electronic databases explored for article collection were PubMed and ScienceDirect. In each database, a search was conducted by title, taking a predefined combination of the following keywords into account: low back pain, core stability, training, sport. The presentation of the articles was carried out in three steps: reading the title, reading the abstracts, and then reading the entire text. Screening processes are summarized through the PRISMA flow chart shown below in Figure 1.

**Inclusion and Exclusion criteria**

Only original articles written in English and published in peer-reviewed journals are considered for inclusion in this review. The publication date limit was from 2011 and is closed until December 2019 in Figure 2.

Various formats of publications such as reviews, abstracts, citations, abstracts of scientific conferences, books, book reviews, editorials, articles, and comments that have not been reviewed, are
excluded. Only the effects of core stability exercises, lumbar lordosis, and lower back pain can be included in the examination. Eligible articles should be conducted with people of all ages. Both qualitative and quantitative articles were taken into account.

Results

Preliminary title and the abstract search revealed 408 articles both through PubMed and through ScienceDirect. After reviewing the abstract, 364 duplicates were removed and 45 articles were considered acceptable for further examination. In addition, an article was added to the entire text that was not found during my initial search, but which was considered relevant. This one article was suggested by another researcher, who found them in the appropriate bibliography. Moreover, one other article was removed due to the use of non-English language and without translation. Of the 28 articles analyzed, 8 were excluded from the review due to the insignificance or unavailability of relevant data. Therefore,

(continued on next page)
In this study, the effects of Pilates exercise on the dynamic balance of young people with back pain and on their postural stability were determined. The training lasted 20 minutes a day, for a period of 30 days. The training consisted of 4 exercises: swimming, stretching the legs, pelvic pressure and kneeling in the opposite legal arm with the legs.

In this study, hypotheses were investigated that motor torso control training in subjects with a rigid tendon leads to anterior pelvic tilt and that there is a relationship between anterior pelvic tilt and tendon stiffness. The experimental group had muscle control treatment for two weeks and the other group did not train. The measurement was performed three times.

The aim of this study was to investigate the relationship between strength, balance and endurance of lumbar extensors in persons with lumbar back pain and in persons without pain in this region.

The study examined the relationship between selective Pilates exercises and stretching exercises, how they affect lumbar back pain, lumbar angle and disability. The treatment lasted six weeks. Improvement was observed in groups that did selective Pilates.

In this study, the task was to compare motor control and stability of the lumbar-pelvic region in professional dancers and non-dancers.

This study examined the effect of Tai Chi on the treatment of lower back pain in people older than 50 years. The program lasted 12 weeks, three times a week for 60 minutes.

The aim of this study was to determine whether athletes with a groin injury in relation to the injured side have an anterior tilt of the pelvis.

In this study, the effects of Pilates exercise on the dynamic balance of young people with back pain and on their postural stability were determined. The training lasted 20 minutes a day, for a period of 30 days. The training consisted of 4 exercises: swimming, stretching the legs, pelvic pressure and kneeling in the opposite legal arm with the legs.

In this study, hypotheses were investigated that motor torso control training in subjects with a rigid tendon leads to anterior pelvic tilt and that there is a relationship between anterior pelvic tilt and tendon stiffness. The aim of this study was to investigate the relationship between strength, balance and endurance of lumbar extensors in persons with lumbar back pain and in persons without pain in this region.

The study examined the relationship between selective Pilates exercises and stretching exercises, how they affect lumbar back pain, lumbar angle and disability. The treatment lasted six weeks. Improvement was observed in groups that did selective Pilates.

In this study, the task was to compare motor control and stability of the lumbar-pelvic region in professional dancers and non-dancers.

This study examined the effect of Tai Chi on the treatment of lower back pain in people older than 50 years. The program lasted 12 weeks, three times a week for 60 minutes.

The aim of this study was to determine whether athletes with a groin injury in relation to the injured side have an anterior tilt of the pelvis.
the torso muscles indicate impaired or reduced neuromuscular control of the body, indicating inhibition of the lower body muscles, which together affect an increased risk of lower back pain (Haxel Bliven & Anderson, 2013).

Reduced perception of rapid activation of trunk muscles during certain movements, negatively affects the control of movements, which increases the mobility of the joints of the lower extremities in an increased volume, in order to maintain adequate stability of the body. Increased chances of injury are given by the muscles that connect the mentioned joints and which are delayed with activation (Willkerson, Giles, & Seibel, 2012). These results clearly support the core stability concept as an important consideration for preventing core and lower extremity injuries in people.

By reviewing the above research, which determines the impact of the effects of basic stability exercises, lumbar lordosis and lower back pain, we can group several results. First group of researchers analyzed the effects of basic stability exercises and prevention of lower back pain and lumbar lordosis using the Pilates program and additional elastic resistance (Yan et al., 2014; Calatayud et al., 2015; Cruz-Diaz et al., 2017; Lopes et al., 2017; Behennah et al., 2018). Based on the results, they were able to plan new projects to prevent LBP and improve the quality of life. Second group of authors dealt with the analysis of programmed training, which was realized over a longer period of time (several months) in the army. Very positive results have appeared after the implemented programs and this type of health prevention in soldiers can be recommended as a cheap way to improve physical fitness Micheo et al., 2012; Teyhen et al., 2013). Third group of authors analyzed the influence of Chinese methods of practicing Tai Chi Chuan and Tai Chi on the prevention of lower back pain (Zou et al., 2019; Liu et al., 2019). Based on core stability testing and APT, a group of authors analyzed lower back pain and lumbar lordosis (Marshall et al., 2011; Trampas et al., 2015; Kliziene et al., 2015; Shamsi et al., 2016; Kuszewski et al., 2018; Behennah et al., 2018; Liu et al., 2019). Fourth group of researchers analyzed the effects of basic stability exercises and prevention of lower back pain and lumbar lordosis in dancers and horse riders (Kline et al., 2013; Nevison & Timmis, 2013; Paris-Alemamy et al., 2018). Other works refer to the classical research of the relationship between the stability of the nucleus and pain in the lower part.

Conclusion

The paper identifies the evaluation of the effectiveness of including the effects of basic core stability exercises in the prevention of lumbar lordosis and lower back pain. Different analyses were compared between people who have lower back pain and people who are painless. It has been determined that by improving the stability of the core and pelvic muscles, regular exercise can improve and eliminate pain in the lower back. The main reasons for the mentioned problems and pains are muscular inactivity in certain parts of the body, which could have arisen in various ways. This was shown not only by the results and analyzes when the intervention and control groups were compared, but also by different professions of people.

These results provide an opportunity to recommend exercise on the stability of the pelvic nucleus and muscles as the simplest and most favorable prevention for lower back pain and lumbar lordosis. The stability of the nucleus helps to overcome the main causes and deprive the body of functional disabilities and pain. Prevention programs based on regular physical activities related to strengthening the stability of the nucleus and pelvic muscles are one of the most effective ways to improve and maintain quality of life, which results in diagnosing activities, mobility, ability to function normally without pain.
